

Question 1.

A school wants to track how many Student objects have been created.

Create a Student class with a name field and a static totalStudents counter.

Each time a student is created, call a register() method that increases the counter by 1.

In Main, create 3 students, call register() for each, then print the total.

Sample output:

```
Ali registered.  
Sara registered.  
Omar registered.  
Total students: 3
```

Question 2

Create a MathHelper class that has two static methods:

- a. square(int n) which returns $n \times n$,
- b. isEven(int n) which returns true if the number is even.

In Main, use them without creating any object.

Hint: Static methods belong to the class itself, not an object — so you call them as ClassName.methodName() directly, no new needed!

Sample output:

```
Square of 5 is: 25
```

```
Is 4 even? true
```

```
Is 7 even? false
```
